A comparison of the response and chromatographic separation obtained using conventional HPLC and UPLC® coupled with oa-TOF has been performed. Utilising UPLC technology and columns packed with particles <2 μm, high efficiency separations can be achieved at high flow rates, allowing superior resolution and sensitivity to be obtained in a shorter analysis time. UPLC generates chromatographic peaks that are typically only several seconds in width, which places demands upon the detection technique to acquire data at an appropriate rate. The fast duty cycle of oa-TOF technology allows 20 spectra/second to be acquired generating sufficient sampling points across a peak to produce a representative response. An application area has been selected, where previous studies have been performed to illustrate the reduced retention times, improved chromatographic resolution and increased MS response.

When a potential pharmaceutical product has been developed, ADME data has to be generated for molecules with potential therapeutic activity. The rate and route of metabolism of the potential compound within the body is required to be determined. As part of a series of studies aimed at developing a better understanding of the factors governing the metabolic fate of xenobiotics, the metabolism of 4-bromoaniline (4-BrA) has been investigated. Using a newly developed bench top oa-TOF mass spectrometer (Figure 1) previously unobserved metabolites were detected supplying new information to the analytical chemist. The high sensitivity of HPLC coupled to an oa-TOF revealed a complex pattern of metabolism with a plethora of previously unidentified minor metabolites. The integral LockSpray™ (as shown in Figure 1) source enabled real time exact mass measurements to be used to identify these minor metabolites in an attempt to obtain a more complete metabolic profile in urine and bile for 4-BrA. Due to the many endogenous and xenobiotic metabolites present, the complete chromatographic separation has not been achieved with conventional chromatography, resulting in long analysis times.

Using UPLC, faster analysis times and better sensitivity have been achieved than was obtained using conventional HPLC.

**DISCUSSION**

The results illustrate the comparisons of UPLC and HPLC combined with oa-TOF-MS for metabolite identification. In metabolite identification analysis, the sample make up consists of hundreds of components ranging from polar to non-polar species. As can be seen from Figure 2 excellent chromatographic separation can be achieved using HPLC, although, an analysis time of 90 minutes is required. In Figure 3 it can be seen that the same sample of rat urine with 4-chloroaniline analysed by UPLC, the speed of analysis has been reduced to less than twenty minutes, equating to a sixty percent reduction in analysis time. It can be seen from Figure 4 where a series of metabolites scans have been selected, for both the UPLC and HPLC oa-TOF-MS analyses, for those analyses performed using UPLC it is clear that chromatographic resolution has been maintained. From these examples it can be seen that a lower plate height is produced using 1.7 μm particles at a 2.1 mm id column at flow rates of 0.6 mL/min leading to improved the peak efficiency resulting in narrower chromatographic peaks. With improved peak efficiency comes better resolution, due to narrower chromatographic peaks leading to increased peak capacity. As can be seen from Figure 4, an example of a UPLC and HPLC oa-TOF-MS extracted mass chromatograms corresponding to metabolite scans B was expanded and overlaid. The metabolites B the base peak widths were 0.48 minutes (HPLC) and 0.12 minutes (UPLC), illustrating a four-fold decrease in baseline peak width. By reducing the peak width this has been utilized to enable faster analysis times whilst maintaining resolution. For this metabolite identification study, three time course periods were analysed as well as the control, this was completed in 85 minutes using UPLC compared to 200 minutes previously obtained with HPLC. Oa-TOF-MS enables fast acquisitions to be performed at 20 spectra per second allowing sufficient points across the superior efficient narrow peaks obtained with UPLC oa-TOF-MS acquisition. An example of the specificity that can be obtained with exact mass measurement is shown in Figure 5, where both b)romine isostere elemental compositions for the 4-chloroanaline hydroxy sulphonate metabolites were determined within 2 ppm. In this study unknowns are being profiled. The combination of low analyte detection with full spectra acquisition and the highly specific nature of exact mass is required to produce complete confidence in analyte identity. UPLC and UPLC oa-TOF-MS offers an unprecedented means of increasing sample throughput with full exact mass spectral information being acquired.

**CONCLUSION**

- UPLC oa-TOF-MS analysis for metabolite identification has been performed with a 60% increase in speed of analysis.
- For metabolite identification UPLC data indicating a four-fold decrease in baseline peak width has been shown enabling time efficient analysis to be achieved without compromising resolution.
- Increased peak efficiency has produced narrower chromatographic peaks and therefore improved peak resolution.
- The LCT Premier with integral LockSpray and independent reference sampling enables the routine acquisition of highly specific data in combination with UPLC.
- Exact mass measurement with ±3 ppm error is achieved routinely.
